

ACCELERATOR EXPERIMENT: Coherent Tune Shift at High Energy
in the Booster

Experimentalists: J. Lackey, F. Mills, A. Ruggiero, M. Shea

Date Performed: October 24, 1974

The measurement of the coherent tune shift at high energy in the Booster has been done under the same operation conditions as specified in EXP-65. Only the vertical tune has been measured by kicking the beam with a notcher. Because of the kick, few percent of the beam intensity were lost. The kick was applied at $t_1 = 8$ msec and $t_2 = 18$ ms after injection. The charge was also measured a little after these times. The fractional tune is displayed vs. beam intensity in Figs. 1 and 2 for $t_2 = 18$ ms and in Fig. 3 for $t_1 = 8$ ms. The beam intensity was changed as explained in EXP-65, either by acting on S1 (Fig. 1) or on QV 25 (Figs. 2 and 3).

Table I summarizes the data. The bunching factor B has been derived by measuring the bunch length (see Figs. 4, 5 and 6). The Laslett coefficients α_M and α_E are the same as calculated in EXP-65. $\Delta v_{\text{calc.}}$ is the tune shift calculated according to the Laslett formula

$$\Delta v = - \frac{N r_p R}{\pi v \gamma} \left[(\alpha_M + \alpha_E) + \frac{\alpha_E}{B \beta^2 \gamma^2} \right]$$

Δv_{meas} is the measured tune shift.

There is a discrepancy between measurement and calculation of ~20% at $t_1 = 8$ ms and ~50% at $t_2 = 18$ ms. The measured shifts resulted larger than the calculated ones.

A.G. Ruggiero

Table I

Time	8 ms	18 ms
β	0.8839	0.9843
γ	2.14	5.66
B	0.2	0.1
$B\beta^2\gamma^2$	0.716	3.10
N		1.0×10^{12}
r_p		1.5347×10^{-18} m
R		75.4717 m
ν		6.8
α_M		0.218 cm^{-2}
α_E		0.0519 cm^{-2}
$(\alpha_M + \alpha_E) + \frac{\alpha_E}{B\beta^2\gamma^2}$	0.342 cm^{-2}	0.287 cm^{-2}
$Nr_p R / \pi \nu \gamma$	0.0236 cm^2	0.0095 cm^2
$\Delta \nu_{\text{calc}}$	-0.0081	-0.0027
$\Delta \nu_{\text{meas}}$	-0.01	-0.005
